# EPIDEMIOLOGY, PATHOLOGY AND TREATMENT OF PARAGONIMIASIS IN VIETNAM

Nguyen Van De

National Institute of Malariology, Parasitology, and Entomology, Ha Noi, Vietnam

**Abstract.** Studies on paragonimiasis have been carried out at 9 sites in 8 provinces of the northern mountainous regions of Vietnam, where the people have the habit of eating undercooked crab. From 1994 to 2000 with 6,576 persons in these endemic areas, the rate of eating raw-crab was 68.1%. Crab examination (species *Potamicus tannanti*) showed an average infection rate with *Paragonimus* metacercaria of 53.6%. With 5,340 stool samples examined by Kato technique, the average infection rate of *Paragonimus* in humans was 1.9%. With 2.216 sputum samples examined by direct and centrifuge methods, the average infection rate of *Paragonimus* was 6.4%. Most of the patients were children (68.5%). The *Paragonimus* infection rate in dogs was 12.1%. Adult worms, collected from dogs in the field and from cats in the laboratory, were identified as *Paragonimus heterotremus* Chen et Hsia 1964 (by electron-microscope and PCR techniques). The main symptoms of paragonimiasis patients was cough (100%), hemoptysis (90.2%), interrupted development (97.7%), no fever (91.7%), chest pain (80.3%), pleural effusion (24.6%), neurological symptoms (4.5%), negative for TB (100%), eosinophilia (90.8%). Chest x-ray examination of the lungs showed nodular shadows (91.8%), ring shadows (90.2%), and more in the lower lobe (82.0%). Paragonimiasis patients were treated by: praziquantel 25 mg/kg/day x 3 days, the cure rate was 68.8%; praziquantel 50 mg/kg/day x 3 days, the cure rate was 75%; and praziquantel 75 mg/kg/day x 2 days, the cure rate was 99.6%.

#### INTRODUCTION

Paragonimiasis is a food-borne trematode disease. There are over 40 species in the *Paragonimus* genus. Over ten of these infect humans. There were 53 species in 21 genera of freshwater crustaceans and 40 species of freshwater snails, which are intermediate hosts of *Paragonimus* (Faust and Russell, 1964). Paragonimiasis is distributed in many countries of the world. Since 1995, paragonimiasis has been reported in 39 countries, especially China, Japan, Korea, Cameroon, Ecuador, and Peru (WHO, 1995; Darren *et al*, 1998; De *et al*, 1998).

The first case of paragonimiasis was reported in Vietnam, in 1906. From 1906 to 1992, over 30 cases of paragonimiasis in Vietnam were reported. The National Institute of Malariology, Parasitology, and Entomology, Ha Noi, commenced studies on the epidemiology, pathology, diagnosis, and treatment of paragonimiasis in some northern mountainous provinces of Vietnam in early 1994. The objectives of the studies were: 1) determination of the epidemiology of paragonimiasis in some northern mountainous areas of Vietnam; 2) Description of pathology of paragonimiasis for diagnosis; 3) Identification of *Paragonimus* species in Vietnam; and 4) Use of praziquantel to treat paragonimiasis in the field.

Correspondence: Nguyen Van De, National Institute of Malariology, Parasitology and Entomology, Ha Noi, Vietnam.

#### MATERIALS AND METHODS

#### Study site

Sin Ho District of Lai Chau Province, Thuan Chau and Moc Chau districts of Son La Province, Da Bac District of Hoa Binh Province, Bao Yen District of Lao Cai Province, Ky Son District of Nghe An Province, Ha Giang City, Van Quan District of Lang Son Province and Luc Yen District of Yen Bai Province were chosen for study.

# **Epidemiological studies**

Human examination. The relationship between the habit of eating undercooked crab and paragonimiasis infections in the population was studied. Stool samples were examined by Kato technique to find *Paragonimus* eggs; sputum examination by direct and centrifuge method to find *Paragonimus* eggs and by Ziehl-Neelsen stain to find TB (*Mycobacterium tuberculosis*).

**Mammal examination.** Stool samples of dogs were examined for *Paragonimus* eggs. Lungs of dogs and cats were examined for adult worms. Cats were experimentally infected with *Paragonimus* metacercariae collected from crabs (25-30 metacercariae/cat).

**Crab examination.** Crabs were collected and species identified, then examined by digestive method with pepsin-acid solution to find *Paragonimus* metacercariae (Thanh, 1995, 1997; Dareen *et al*, 1997).

**Snail examination.** Snails were collected and species identified, then directly examined for *Paragonimus* cercariae.

#### Clinical studies

Clinical symptoms of patients infected with *Paragonimus*. The paragonimiasis patients were physically examined. The main clinical symptoms were cough, hemoptysis, chest pain, no fever, interrupted development, and pleural effusion.

Sub-clinical investigations of paragonimiasis patients. Besides stool and sputum samples examined to find *Paragonimus* eggs, blood samples were taken for examination of eosinophilia, and lung x-rays were done.

# Treatment of patients infected with Paragonimus

Patients found to have *Paragonimus* eggs in sputum or stool were selected for study. All patients were treated with praziquantel 25 mg/kg/day x 3 days or 50 mg/kg/day x 3 days, and 75 mg/kg/day x 2 days. The efficacy of the regimen was determined by sputum and stool examination one month and one year after treatment.

# **Identification of species**

Species were identified by morphology (electron-microsope) (Kino et al, 1995, De et al, 1997) and molecular technique (PCR with mitochondrial-encoded cox1 gene) (Hoa et al, 2001). Samples collected from different hosts (human, reservoir host, and crab) in Lai Chau, Son La, Lao Cai and Hoa Binh provinces were amplified using polymerase chain reaction (PCR) and comparatively aligned with the known corresponding sequences of Paragonimus

heterotremus (geographical origin: China and Thailand) and representative species of the *Paragonimus* genus (GenBank and published data).

#### RESULTS

#### **Human infection rate**

The total number of people reviewed was 6,505 of which 68% (range 40.1-90.0%) anwered that they ate raw crab. Stools of 5,340 indiduals were examined with 1.9% positive for *Paragonimus*. Sputums (2,216 samples) were also examined, 6.4% gave positive results. The rate of raw-crab eating and results of stool and sputum examinations in each study site are presented in Table 1.

At the 9 study sites, the prevalence of paragonimiasis was 0.3-15.7% (Fig 1). Of the 90 sputum samples examined, 100% were negative for TB.

# Infection rates in snails, dogs and crabs

At all 9 study sites, *Potamicus* crab infection by *Paragonimus* metacercariae was 8.7-98.1%. The percentage of *Melanoides* snail-infected *Paragonimus* cercariae was 1.4-5% in 5 of the 9 study sites; the infection rate for *Canis familiaris* was 2.9-26.1% in 5 of the 9 study sites (Table 2). For 145 *Parathephusa* crabs in the study sites, no *Paragonimus* metacercaria was found.

# Species identification of parasite and intermediate host

Adult worms were identified as *Paragonimus* heterotremus Chen et Hsia 1964.

Potamicus tannanti crab and Melanoides sp were intermediate hosts of Paragonimus in Vietnam.

75 mg/kg/day x 2days	178	177	99.4

### Pathological information

**Paragonimiasis patients.** The 178 paragonimiasis patients included 68.5% children (under 15 years old). Positive for *Paragonimus* eggs was 100%, chronic cough 100%, hemoptysis 90.2%, interrupted development 97.7%, no fever 91.7%, chest pain 80.3%, no weight loss 99%, pleural effusion 24.6%, eosinophilia 90.8%, nodular shadow 91.8%, ring shadow 90.2%, lung lesion in the lower lobe 82.0%.

**Infected cats.** *Paragonimus* eggs appeared in the stools of infected cats 50-52 days post-infection. Most adult worms parasitized the lower lobes (90.5%). Most lung abscesses contained 2 adult worms (13/19 abscesses).

#### Efficacy of praziquantel

The efficacy of paraziquantel at different dosages is presented in Table 3. Some side-effects of praziquantel treatment were noted: dizziness, headache, nausea, and vomiting (4.1-12.5%), which disappeared some hours later.

Fig 2- Nucleotides of the mitochondrial-encoded cox1 gene of Paragonimus sp.

Molecular-based analysis revealed that the *Paragonimus* sp of Vietnam is *Paragonimus heterotremus* Chen et Hsia, 1964, showing high nucleotide similarity to the China and Thailand strains (over 99%) (Fig 2). Phylogenetic analysis uniquely grouped the Vietnamese *Paragonimus* sp with the *Paragonimus heterotremus* of China and Thailand (Fig 3).

#### DISCUSSION

In the 9 study sites, the majority of the population had the habit of eating raw crab (68.1%). Crabs in 9/9 studied sites were infected with *Paragonimus* larva (78.7-98.1%). This habit is a risk for paragonimiasis, and threatens many people

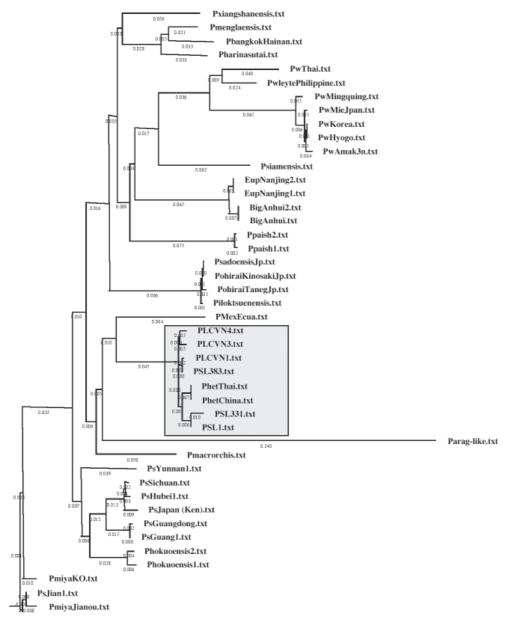

Fig 3- Phylogenetic analysis of unique groups of Vietnamese *Paragonimus* sp with the *Paragonimus heterotremus* of China, Thailand, and others.

living in endemic areas. Moreover, the infection rate of reservoir hosts (dogs) was also high (2.9-26.1%) in 5/9 of the studied sites. This is a major local health problem that is very difficult to prevent. The prevalence of paragonimiasis in humans at 9/9 studied sites was 0.3-15.7%.

The main symptoms of patients were chronic cough (100%), hemoptysis (90.2%), and tuberculosis-

like chest pain (80.3%). Those symptoms are discontinuously developed over time (97.7%). All patients (100%) in the study were negative for TB, 91.7% had no fever, none lost weight, and eosinophilia was present in 90.8% of the patients; the result of Uchiyama *et al* (1999), was 81.7% for eosinophilia.

Nodular ring shadows in the lungs were shown by chest x-ray examination as in tuberculosis but more

Vol 35 (Suppl 1) 2004 335

often in the lower lobes, as in the laboratory results with infected cats, similar to the result of Toscano *et al* (1995).

Among paragonimiasis patients treated with antituberculosis drugs, the youngest paragonimiasis patient was 1.5 years old and the oldest was 73 (De *et al*, 1999).

Diagnosis of paragonimiasis is confirmed by identification of *Paragonimus* eggs in sputum, stool or pleural effusion samples. However, the number of paragonimiasis patients may be larger than this study indicated because the rate of positive samples was 40% (Faust, 1949; Toscano, 1995).

Adult worms were identified as *Paragonimus heterotremus* by electron-microscope and confirmed by PCR technique (Hoa, 2001). This species was described as distributed in China (Chen Hsia, 1964), Thailand (Miyazaki and Harinasuta, 1966) and Lao PDR (Miyazaki and Fontan, 1970; Vanijanonta, 1984). The efficacy of praziquantel for patients infected with *Paragonimus* was high, and its use was safe in the field.

#### Conclusion

The prevalence of paragonimus in the 9 study sites of 8 northern mountainous provinces of Vietnam was 0.3-15.7% (Lai Chau, Son La, Hoa Binh, Lao Cai, Ha Giang, Lang Son, Yen Bai and Nghe An), where 42-97.3% of people had the habit of eating raw crab. Adult worms were identified as *Paragonimus heterotremus* (Chen et Hsia, 1964). The infection rate of *Paragonimus* larvae in *Potamicus tannanti* crabs was 53.6% (8.7-98.1%). The infection rate of *Paragonimus* cercaria in *Melanoides* snail was 1.7% (0-5.0%).

The main symptoms of paragonimiasis were hemoptysis (90.2%), with interrupted development (97.7%), no fever (91.7%), chest pain (80.3%), pleural effusion (24.6%), negative for TB (100%), eosinophilia (90.8%), nodular shadows (91.8%), ring shadows (90.2%), and lesion in the lower lobes (82.0%) of the lungs by chest x-ray examination.

Paragonimiasis patients were treated with praziquantel 25mg/kg/day x 3 days, and the cure rate was 68.8%; by praziquantel 50mg/kg/day x 3 days, 75%, and by praziquantel 75mg/kg/day x 2 days, 99.4%, and safe.

Molecular-based analysis confirmed that the Paragonimus sp of Vietnam is Paragonimus hete-

rotremus Chen et Hsia, 1964. Phylogenetic analysis uniquely groups the Vietnamese *Paragonimus* sp with the *Paragonimus heterotremus* of China and Thailand.
