Abstract. Diagnosis of *Pythium* keratitis is problematic due to the difficulty in obtaining a culture report resulting in unnecessarily prolonged usage of antimicrobial medication due to misdiagnosis. This study evaluated and compared nested PCR technique with culture and immunoperoxidase staining assays of *Pythium insidiosum* in paraffin-embedded corneal tissues from patients with suspected fungal keratitis. Six of 51 pathological reports compatible with fungal infection and 6 of 48 culture-proven fungal keratitis were identified as *Pythium*. Twenty-seven specimens were PCR-positive for *Pythium insidiosum*. In comparison with fungal culture for *P. insidiosum*, PCR had 83% sensitivity and 77% specificity with fair agreement (Kappa score of 0.227, \(p = 0.001\)). The mean age of PCR-positive is younger than PCR-negative group and there is a female preponderance in *Pythium*-infected group (\(p = 0.002\) and \(p = 0.004\), respectively). Nineteen specimens had positive results using immunoperoxidase staining assay with fair agreement to culture method (Kappa 0.340, \(p < 0.001\)), and 83% sensitivity, 85% specificity and 85% accuracy (95% CI: 76.7-90.7). PCR-based technique compared with culture and/or immunoperoxidase staining assay had 91.7% sensitivity, 81.8% specificity and 83% accuracy (95% CI: 74.5-89.1) with moderate agreement (Kappa 0.477, \(p < 0.001\)). Thus nested PCR detection of *P. insidiosum* should be employed in preliminary diagnosis of *Pythium* keratitis in order to initiate proper management.
